

Created a downtime detector to monitor drops on our corporate wifi by installing Uptime Kuma onto a Raspberry Pi using docker. I had the device ping both our Firewall and Google.

We were being alerted by some staff of virtual meetings dropping every 10 minutes or so. Normal tests were not catching anything, so I decided to find a way to consistently ping our Firewall and ping externally to see if I could notice anything. With this monitoring, we were able to see that our corporate wifi was dropping every 10-12 minutes. After further research we found an authentication setting that was causing the problem. Now our wifi is back to being consistently up. I plan on using this device in the future at other sites if necessary too. Below is a screenshot of the Uptime Kuma dashboard after everything was running smoothly.
